ABSTRACT

The **Real Estate Property Search and Recommendation System** is a Data Structures and Algorithms (DSA) based project developed to efficiently search and filter large collections of real estate properties. Real estate platforms contain thousands of listings, making it difficult for buyers to quickly find properties that match their requirements. The system addresses this problem by organizing property information using suitable data structures and efficient algorithms. The system stores details such as **location, price, property type, number of bedrooms, area, and amenities**. Data structures such as arrays, linked lists, hash tables, trees, and priority queues can be used to manage property records. Searching and sorting algorithms help users filter properties based on location, price range, size, and amenities. Techniques such as **binary search and hashing** improve search performance, while sorting algorithms can rank properties based on price, area, or relevance. The project demonstrates the practical application of **searching, sorting, hashing, data structures, and algorithm analysis** to provide faster and more efficient property discovery.
